Problem #1 (Monte Carlo Error)

Use Monte Carlo simulation to price a European call option in the Black-Scholes model with the following parameters: $S_0 = 100, \sigma = 0.30, r = 0.05, T = 1,$ and $K = 100.$

a. Use (exact) simulation based on the closed-form solution of geometric Brownian motion. Use $n = 100000$ paths.

Clearly describe the steps of your simulation procedure, and provide formulas for the Monte Carlo estimator and a corresponding 95% confidence interval. Report both the estimator and the confidence interval. Does the confidence interval contain the true price of the option?

Procedure

1. **Simulation of Stock Prices**: According to BSM, the stock process S_t at future time t is as follows:

$$S_t = S_0 \exp\{(r - \frac{1}{2}\sigma^2)T + \sigma\sqrt{T}Z_T\}$$

where

- S_0 = initial stock price
- r = rfr (e.g., 3-month UST)
- σ = vol
- T = time till maturity
- Z_T = standard normal $\sim \mathcal{N}(0, 1)$

2. **Payoff Calculation**: For a call option, the payoff at maturity is $(S_T - K)_+$ where K is the strike price. For puts, it's the converse $(K - S_T)_+$.

3. **MC Estimator**: The price of the option is the present value of the expected payoff under the risk-neutral measure $\mathbb{Q}$, which is estimated as the average of the discounted payoffs across all simulated paths:

$$P = e^{-rT}\mathbb{E}^Q[f(S_t)], \text{ where } f \text{ is the payoff function.}$$

$$\ldots$$

$$\hat{C} = \exp\{(-rT)\}\frac{1}{n}\sum_{i=1}^{n} f(S_t)$$

4. **CI**: The 95% confidence interval for the true option price is given by

$$\hat{C} \pm z_{\alpha/2} \cdot SE$$

where $\alpha = 0.05$ and $SE = \text{standard error}$. Therefore,

$$\hat{C} = 1.96 \cdot \frac{\sigma_{\hat{C}}}{\sqrt{n}}$$

where $\sigma_{\hat{C}}$ is the standard deviation of the stimulated payoffs.

5. **True Price Comparison**: The true price of the option can be calculated using the BSM closed-form solution. We compare the confidence interval obtained from the Monte Carlo simulation with the true price to see if it contains the true price.

$$C(s,t) = S_0 N(d_1) - Ke^{-rT}N(d_2)$$

$$d_1 = \frac{\ln(\frac{S_0}{K}) + (r + \frac{1}{2}\sigma^2)T}{\sigma\sqrt{T}}$$

$$d_2 = d_1 - \sigma\sqrt{T}$$

In [ ]:

```
import numpy as np
from scipy.stats import norm

def simulate_stock_prices(S_0: float, sigma: float, r: float, T: float, n: int) ->
    """
    Simulate end stock prices using the closed-form solution of GBM.

    Parameters:
    - S0: Initial stock price
    - sigma: Volatility of the stock price
    - r: Risk-free interest rate
    - T: Time to maturity
    - n: Number of paths to simulate

    Returns:
    - A numpy array containing simulated end stock prices.
    """

    Z_T = np.random.normal(0, 1, n)
    S_T = S_0 * np.exp((r - 0.5 * sigma**2) * T + sigma * np.sqrt(T) * Z_T)
    return S_T

def monte_carlo_option_pricing(S_0: float, K: float, sigma: float, r: float, T: flo
    """
```

```
    Price a European call option using Monte Carlo simulation with geometric Browni

    Parameters:
    - S0: Initial stock price
    - K: Strike price
    - sigma: Volatility of the stock price
    - r: Risk-free interest rate
    - T: Time to maturity
    - n: Number of paths to simulate

    Returns:
    - The estimated option price and its 95% confidence interval as a tuple.
    """

    S_T = simulate_stock_prices(S_0, sigma, r, T, n)
    call_payoff = np.maximum(S_T - K, 0)

    option_price_estimate = np.exp(-r * T) * np.mean(call_payoff)

    standard_error = np.std(call_payoff) * np.exp(-r * T) / np.sqrt(n)

    confidence_interval = (option_price_estimate - 1.96 * standard_error, option_pr

    return option_price_estimate, confidence_interval

# Parameters
S_0 = 100  # Initial stock price
sigma = 0.30  # Volatility
r = 0.05  # Risk-free rate
T = 1  # Time to maturity
K = 100  # Strike price
n = 100000  # Number of paths

# Running the Monte Carlo simulation.
option_price, confidence_interval = monte_carlo_option_pricing(S_0, K, sigma, r, T,
option_price, confidence_interval
```

Out[ ]: (14.257021121810503, (14.116859508454846, 14.39718273516616))

In [ ]:

```
def black_scholes_call_price(S_0: float, K: float, T: float, r: float, sigma: float
    """
    Calculate the Black-Scholes-Merton price of a European call option.

    Parameters:
    - S0: Current stock price
    - K: Strike price
    - T: Time to maturity (in years)
    - r: Risk-free interest rate (annualized)
    - sigma: Volatility of the stock price (annualized)

    Returns:
    - The Black-Scholes-Merton price of the call option.
    """
    d1 = (np.log(S_0 / K) + (r + 0.5 * sigma**2) * T) / (sigma * np.sqrt(T))
    d2 = d1 - sigma * np.sqrt(T)
```

```
    call_price = (S_0 * norm.cdf(d1)) - (K * np.exp(-r * T) * norm.cdf(d2))

    return call_price

# Parameters for the BSM model
S0 = 100    # Initial stock price
K = 100     # Strike price
T = 1       # Time to maturity in years
r = 0.05    # Risk-free interest rate
sigma = 0.30  # Volatility

# Calculate the BSM call price.
bsm_call_price = black_scholes_call_price(S0, K, T, r, sigma)
print(f"{bsm_call_price:.3f}")
```

```
14.231
```

As seen above, the CI **contains the true price** of the (call) option as well as the estimator: $14.231 \cap 14.257 \in (14.116859508454846, 14.39718273516616)$.
